## NOVEL COMPOUNDS

The invention relates to novel compounds having pharmacological activity, to processes for their preparation, to pharmaceutical preparations containing them and to their use in medicine.

Renin is a natural enzyme, disorders in relation to which are implicated in many cases of hypertension. It is released into the blood from the kidney, and cleaves from a blood glycoprotein a decapeptide known as angiotensin-I. Circulating angiotensin-I is cleaved in plasma, and in lung, kidney and other tissues to an octapeptide, angiotensin-II, which raises blood pressure both directly by causing arteriolar constriction and indirectly by stimulating release of the sodium-retaining hormone aldosterone from the adrenal gland and thus causing a rise in extracellular fluid volume. The latter effect is caused by angiotensin-II itself or a heptapeptide cleavage product angiotensin-III.

Inhibitors of renin have been described as useful in the treatment of hypertension.

A group of compounds has now been discovered, which inhibit the enzyme renin and therefore have potential blood pressure lowering activity, useful in the treatment of hypertension. Compounds having an associated mechanism of action have also been described as possessing anti-retroviral activity and the present compounds may therefore be of potential use in the treatment of diseases caused by retroviruses including human immunodeficiency virus (HIV-1 and 2) and HTLV I and II. They may also be of potential use in the treatment of other cardiovascular disorders, such as congestive heart failure, and have beneficial effects on learning and memory and mood elevation activity, of potential use in the treatment of CNS disorders such as Alzheimer's disease and depression; they may also be of potential use in the treatment of glaucoma.

The compounds of formula (I) and (IA) wherein  $E$  is attached to  $Z_1/Z_2/Z_3/Z_4/Z_5$  when  $CH$ , have at least one asymmetric centre in addition to those attached to  $R_1$  and  $R_2$  (in  $X$  and  $Y$ ) and  $R_3$  and those indicated in formula (IA), and are therefore capable of existing in more than one stereoisomeric form. The invention extends to each of these forms and to mixtures thereof. Preferably the configuration at the carbon atoms bearing  $R_1$ ,  $R_2$  and  $R_3$  is the (S)-configuration.

It will be appreciated that, when the optional bond depicted in formula (I) is present, the compounds are capable of existing in  $E$  and  $Z$  ( trans and cis ) forms. The invention extends to each of these forms and to mixtures thereof.

The compounds of the invention are preferably in pharmaceutically acceptable form. By pharmaceutically acceptable form is meant, inter alia, of a pharmaceutically acceptable level of purity excluding normal pharmaceutical additives such as diluents and carriers, and including no material considered toxic at normal dosage levels. A pharmaceutically acceptable level of purity will generally be at least 50% excluding normal pharmaceutical additives, preferably 75%, more preferably 90% and still more preferably 95%.

A compound of the invention may be prepared by those methods known in the art for the synthesis of compounds of analogous structure, such as peptides, and in this regard reference is made, by way of illustration only, to the literature reference: S.R. Pettit, " Synthetic Peptides " (Elsevier Scientific Publishing Co. 1976).

The present invention also provides a compound of the present invention which has been prepared synthetically.

A compound of the present invention may, for example, be formed by the sequential coupling of appropriate amino acids with the acid of formula (II):

wherein  $R_a'$  and  $R_b'$  are  $R_a$  and  $R_b$  respectively or groups or atoms convertible thereto; or by the initial preparation and subsequent coupling of peptide subunits with the acid of formula (II), the subunits themselves prepared in stepwise manner; in either case classical solution chemistry methods analogous to those used in peptide synthesis, may be employed.

The coupling reactions may be effected by, for example, activating the reacting carboxyl group of th

acid of formula (II) or amino acid, and reacting this with the amino group of the substrate unit. Details of suitable, optional activating and protecting (masking) groups and of suitable reaction conditions (for the coupling reactions and for the introduction and removal of protecting groups) giving, preferably, the minimum of racemisation, may be found in the above-referenced literature.

It will be appreciated that, when A is other than -CONH- or -COO-, the C-terminus group is other than an amino acid, in which case the coupling is carried out with an appropriate other precursor, as described in the aforementioned literature references 2., 5., 6. and 7.

Accordingly, the present invention further provides a process for the preparation of a compound of formula (I) or a pharmaceutically acceptable salt thereof which comprises reacting a reagent of the formula (III):

wherein  $R_a'$  and  $R_b'$  are  $R_a$  and  $R_b$  respectively or groups or atoms convertible thereto;  $A^1$  is absent or represents an appropriate amino acid or dipeptide unit; J is OH or a leaving group; and the remaining variables are as hereinbefore defined; with a reagent of the formula (IV):

wherein

$A^2$  is absent or represents an appropriate amino acid or dipeptide unit, such that  $A^1 + A^2$  is -NHCHR<sub>1</sub>CONHCHR<sub>2</sub>CO-; and the remaining variables are as hereinbefore defined; and thereafter, if desired or necessary deprotecting (within  $A^1$  or  $A^2$ ) of the products, and/or converting  $Z_1, Z_2, Z_3, Z_4$  or  $Z_5$  to other  $Z_1, Z_2, Z_3, Z_4$  or  $Z_5$ ,  $R_a/R_b'$  to  $R_a$  and/or  $R_b$  and/or forming a pharmaceutically acceptable salt thereof.

Suitable examples of J when a leaving group include halo, such as chloro or bromo, and other suitable groups which are displaceable by an amino nucleophile, such as C<sub>1-6</sub> alkoxy carbonyloxy.

It is generally preferred, especially when  $A^1$  is not absent, however, that J is OH, and a suitable coupling reagent or dehydrating catalyst is used to effect the reaction, such as N,N-dicyclohexylcarbodiimide and those described in the Descriptions and Examples hereinafter.

Deprotection of  $A^1$  and/or  $A^2$  takes place conventionally, in accordance with the particular protecting group(s) employed.

Pharmaceutically acceptable salts may be formed conventionally.

$Z_1, Z_2, Z_3, Z_4$  or  $Z_5$  when S or SO may be converted to SO or SO<sub>2</sub> respectively (or S to SO<sub>2</sub>) by conventional oxidation methods, such as those described hereinafter for conversion (vi) for  $R_a/R_b$ .

It will be apparent that compounds of the formula (I) containing an  $R_a/R_b'$  group which is other than  $R_a/R_b$  and which is convertible to  $R_a/R_b$  group, are useful novel intermediates. A number of such conversions is possible, not only for the final product compounds of formula (1) when  $R_a/R_b'$  are other than  $R_a/R_b$ , but also within  $R_a/R_b'$ , and also for their intermediates as follows:

(i) a hydrogen substituent is convertible to a nitro substituent by nitration;

- (ii) a nitro substituent is convertible to an amino substituent by reduction;  
 (iii) a C<sub>1-7</sub> acylamino substituent is convertible to an amino substituent by deacylation;  
 (iv) an amino substituent is convertible to a C<sub>1-7</sub> acylamino substituent by acylation with a carboxylic acid derivative;  
 5 (v) a hydrogen substituent is convertible to a halogen substituent by halogenation;  
 (vi) an C<sub>1-6</sub> alkylthio or a C<sub>1-6</sub> alkylsulphinyl substituent is convertible to a C<sub>1-6</sub> alkylsulphinyl or C<sub>1-6</sub> alkylsulphonyl substituent respectively, by oxidation;  
 (vii) an amino, aminosulphonyl, or NHCONH<sub>2</sub> substituent is convertible to a corresponding substituent which is substituted by one or two alkyl groups, by N-alkylation;  
 10 (viii) an amino substituent is convertible to a group NHCONH<sub>2</sub>, by reaction with potassium cyanate and acid;  
 (ix) a hydrogen substituent is convertible to an aminosulphonyl substituent by treatment with ClSO<sub>3</sub>H followed by HNR<sub>5</sub>R<sub>6</sub>;  
 (x) a cyano substituent may be converted to an aminomethyl substituent by reduction;  
 15 (xi) a bromo substituent may be converted to a cyano substituent by reaction with copper(I) cyanide.

Conversions (i) to (xi) are only exemplary and are not exhaustive of the possibilities. It will be appreciated that it is often desirable to carry out these conversions at an earlier stage, in the intermediate acid of formula (II), especially in regard to conversion (iii).

In regard to (i), nitration is carried out in accordance with known procedures.

- 20 In regard to (ii), the reduction is carried out with a suitable reducing agent, such as that suitable for reducing nitroanisole to aminoanisole.

In regard to (iii), deacylation is carried out by treatment with a base, such as an alkali metal hydroxide.

In regard to (iv), the acylation is carried out with an acylating agent, such as the corresponding acid or acid chloride. Formylation is carried out with the free acid.

- 25 In regard to (v), halogenation is carried out with conventional halogenating agents.

In regard to (vi), oxidation is carried out at below ambient temperatures in a non-aqueous solvent, such as a chlorinated hydrocarbon, in the presence of an organic peracid, such as 3-chloroperoxybenzoic acid, or in water in the presence of a soluble strong inorganic oxidant, such as an alkali metal permanganate or with aqueous hydrogen peroxide.

- 40 Compounds of the general formulae (II) and (III) may themselves be prepared by standard techniques analogous to those described above.

The acids of formula (II) are either known compounds or are prepared by analogous methods to these and for structurally similar known compounds.

The preparation of the amino acid of formula (V):

45

50

is described in J. Med. Chem 1985, 28, 1779-1790.

As regards the appropriate corresponding intermediates to those of formula (V), including those wherein A is other than -CONH-, reference is hereby made to the literature references 2. to 7. listed hereinbefore.

- 55 It will be appreciated that protected forms of compounds of the present invention are novel intermediates and form an aspect of the invention.

A particularly suitable method of preparation of the compounds of the present invention are as described in the Description and Examples hereinafter. The couplings may be carried out sequentially

beginning by coupling the acid of formula (II) with, for example, phenylalanine or 1-naphthylalanine, followed by coupling with Y, for example, leucine or histidine, and finally, coupling with the amino acid of formula (V). In a preferred aspect, however, either the acid of formula (II) is coupled with a tripeptide unit formed between the amino acid of formula (V); leucine, histidine or other R<sub>2</sub> containing amino acid; and phenylalanine or naphthylalanine; or alternatively the acid of formula (II) is coupled with phenylalanine or naphthylalanine and this is coupled with a dipeptide unit formed between the R<sub>2</sub> containing amino acid and the amino acid of formula (V).

As mentioned previously the compounds of the invention have been found to be renin inhibitors, and therefore they are of potential use in the treatment of hypertension. They may also be of potential use in the other diseases and disorders hereinbefore referred to.

The present invention also provides a pharmaceutical composition which comprises a compound of formula (I) or a pharmaceutically acceptable salt thereof, and a pharmaceutically acceptable carrier. In particular, the present invention provides an anti-hypertensive pharmaceutical composition which comprises an anti-hypertensive effective amount of a compound of formula (I) or a pharmaceutically acceptable salt thereof, and a pharmaceutically acceptable carrier.

The compositions are preferably adapted for oral administration. However, they may be adapted for other modes of administration, for example parenteral administration for patients suffering from heart failure. Other alternative modes of administration include sublingual or transdermal administration.

The compositions may be in the form of tablets, capsules, powders, granules, lozenges, suppositories, reconstitutable powders, or liquid preparations, such as oral or sterile parenteral solutions or suspensions.

In order to obtain consistency of administration it is preferred that a composition of the invention is in the form of a unit dose.

Unit dose presentation forms for oral administration may be tablets and capsules and may contain conventional excipients such as binding agents, for example syrup, acacia, gelatin, sorbitol, tragacanth, or polyvinylpyrrolidone; fillers, for example lactose, sugar, maize-starch, calcium phosphate, sorbitol or glycine; tableting lubricants, for example magnesium stearate; disintegrants, for example starch, polyvinylpyrrolidone, sodium starch glycollate or microcrystalline cellulose; or pharmaceutically acceptable wetting agents such as sodium lauryl sulphate.

The solid oral compositions may be prepared by conventional methods of blending, filling or tableting. Repeated blending operations may be used to distribute the active agent throughout those compositions employing large quantities of fillers. Such operations are of course conventional in the art. The tablets may be coated according to methods well known in normal pharmaceutical practice, in particular with an enteric coating.

Oral liquid preparations may be in the form of, for example, emulsions, syrups, or elixirs, or may be presented as a dry product for reconstitution with water or other suitable vehicle before use. Such liquid preparations may contain conventional additives such as suspending agents, for example sorbitol, syrup, methyl cellulose, gelatin, hydroxyethylcellulose, carboxymethylcellulose, aluminium stearate gel, hydrogenated edible fats; emulsifying agents, for example lecithin, sorbitan monooleate, or acacia; non-aqueous vehicles (which may include edible oils), for example almond oil, fractionated coconut oil, oily esters such as esters of glycerine, propylene glycol, or ethyl alcohol; preservatives, for example methyl or propyl p-hydroxybenzoate or sorbic acid; and if desired conventional flavouring or colouring agents.

For parenteral administration, fluid unit dosage forms are prepared utilizing the compound and a sterile vehicle, and, depending on the concentration used, can be either suspended or dissolved in the vehicle. In preparing solutions the compound can be dissolved in water for injection and filter sterilized before filling into a suitable vial or ampoule and sealing. Advantageously, adjuvants such as a local anaesthetic, a preservative and buffering agents can be dissolved in the vehicle. To enhance the stability, the composition can be frozen after filling into the vial and the water removed under vacuum. Parenteral suspensions are prepared in substantially the same manner, except that the compound is suspended in the vehicle instead of being dissolved, and sterilization cannot be accomplished by filtration. The compound can be sterilized by exposure to ethylene oxide before suspending in the sterile vehicle. Advantageously, a surfactant or wetting agent is included in the composition to facilitate uniform distribution of the compound.

The compositions may contain from 0.1% to 99% by weight, preferably from 10-60% by weight, of the active material, depending on the method of administration.

The present invention further provides a method of prophylaxis or treatment of hypertension in mammals including man, which comprises administering to the suffering mammal an anti-hypertensively effective amount of a compound of formula (I) or a pharmaceutically acceptable salt thereof.

An effective amount will depend on the relative efficacy of the compounds of the present invention, the severity of the hypertension being treated and the weight of the sufferer. However, a unit dose form of a

composition of the invention may contain from 0.1 to 500 mg of a compound of the invention and more usually from 1 to 100 mg, for example 2 to 50 mg such as 2, 3, 4, 5, 10, 20 or 30mg. Such compositions may be administered from 1 to 6 times a day, more usually from 2 to 4 times a day, in a manner such that the daily dose is from 1 to 1000mg for a 70 kg human adult and more particularly from 5 to 500 mg.

5 No toxicological effects are indicated at the aforementioned dosage ranges.

The present invention further provides a compound of formula (I) or a pharmaceutically acceptable salt thereof for use in the treatment or prophylaxis of hypertension.

The following Description relates to the preparation of intermediates and the following Examples relate to the preparation of compounds of formula (I).

After stirring for a further 20 min, 4-chromanone (4.58g) was added dropwise in dry dimethoxyethane (15ml). The solution was stirred for 16h and poured into water. The product was extracted into ether, dried (Na<sub>2</sub>SO<sub>4</sub>), and evaporated in vacuo. Chromatography on silica gel using 20% ethyl acetate in petroleum ether (b.p.60-80°C) gave the title compound (1.83g) as a colourless oil. NMR showed this to be a ca 2:1 mixture of isomers.

2-Amino-4-methylphenol (5.00g) and pyridine (6.6ml) were stirred in dichloromethane (100ml) in ice, as chloroacetyl chloride (3.4ml) was added dropwise. The mixture was stirred for 16h, when water (100 ml) was added. After stirring for a further 0.5h, the layers were separated. The aqueous portion was acidified (5M hydrochloric acid) and extracted with chloroform, and then filtered. The grey solid so isolated was washed with water and dried in vacuo. Recrystallisation from methanol/chloroform then gave the title compound (2.08g) as an off-white powder.

(b) 2,3-Dihydro-6-methyl-3-oxo-4H-1,4-benzoxazine

To a suspension of 2-(chloroacetyl-amino)-4-methylphenol (3.24g) in ethanol (35ml) was added sodium hydroxide (0.85g) in water (5ml). The mixture was swirled until homogeneous, left to stand for 2h, and diluted with water (500ml). Filtration and drying in vacuo then gave the title compound (2.41g) as a slightly pink solid.

#### Biological Data

##### In vitro human renin inhibition

Renin inhibitory activity was estimated as the percentage change in renin activity in human plasma in the presence and absence of compound. The source of plasma was blood taken from healthy volunteers. Renin activity was defined by the difference in angiotensin I levels between two halves of a sample, one incubated at 37° and the other at 4° for 2 h. Angiotensin I levels were measured using a  $^{125}\text{I}$ -angiotensin I radioimmunoassay kit (NEN/DuPont, Stevenage). Results were calculated as the mean of at least two, duplicate determinations and  $\text{IC}_{50}$  values were calculated by linear regression analysis of at least three concentrations of compound.

45

The results were as follows:

Compound	$\text{IC}_{50}$ (nm)
E1	47
E2	220
E7	13
E11	25
E15	42
E18	8
